### Regulatory Capital Principles

### Risk measures as regulatory capital principles

A (regulatory) risk measure is a functional  $\rho : \mathcal{X} \to (-\infty, \infty]$ which calculates the amount of regulatory capital of a financial institution taking a risk (random loss) X in a fixed period.

- $(\Omega, \mathcal{F}, \mathbb{P})$  is an atomless probability space
- $\mathcal{X}$  is a convex cone of random variables

• e.g. 
$$\mathcal{X} = L^q(\Omega, \mathcal{F}, \mathbb{P}), \ q \in [1, \infty]$$

•  $X \in \mathcal{X}$  represent loss/profit (discounted to present)

### Very general question

What is a good risk measure to use?

### Value-at-Risk and Expected Shortfall

Value-at-Risk (VaR) at level  $p \in (0, 1)$ 

 $\operatorname{VaR}_{p}: L^{0} \to \mathbb{R},$ 

$$\operatorname{VaR}_p(X) = \inf\{x \in \mathbb{R} : \mathbb{P}(X \le x) \ge p\}.$$

Expected Shortfall (ES/TVaR/CVaR/AVaR) at level  $p \in (0, 1)$ 

 $\mathrm{ES}_{\beta}: L^1 \to \mathbb{R},$ 

$$\mathrm{ES}_p(X) = rac{1}{1-p} \int_p^1 \mathrm{VaR}_q(X) \mathrm{d} q, \ \ p \in (0,1).$$

### Value-at-Risk and Expected Shortfall

The ongoing debate on "VaR versus ES":

- Basel III (mixed; in transition from VaR to ES as standard metric for market risk<sup>1</sup>)
- Solvency II (VaR based)
- Swiss Solvency Test (ES based)

<sup>1</sup>e.g. Basel Committee on Banking Supervision: Standards, January 2016, Minimum capital requirements for Market Risk. Ruodu Wang (vang@uwaterloo.ca) Risk Aversion in Regulatory Capital Principles

|               |                    |             |                  |              |             |            |

### Value-at-Risk and Expected Shortfall

Many perspectives

- regulator's versus firms' standpoints
- economic interpretation
- statistical issues: estimation, robustness, backtesting, model uncertainty
- computation, simulation and optimization
- systemic risk
- There is no single "perfect" risk measure

Some academic references

- Embrechts et al. (2014)
- Emmer-Kratz-Tasche (2015)

### Standard Properties of Risk Measures

Some standard properties of risk measures

- (M) Monotonicity:  $\rho(X) \le \rho(Y)$  for  $X, Y \in \mathcal{X}, X \le Y$  almost surely;
- (TI) Translation-invariance:  $\rho(X m) = \rho(X) m$  for all  $m \in \mathbb{R}$ and  $X \in \mathcal{X}$ .
- (LI) Law-invariance:  $\rho(X) = \rho(Y)$  if  $X, Y \in \mathcal{X}$  and  $X \stackrel{d}{=} Y$ .

### Definition 1

A monetary risk measure is a functional on  ${\cal X}$  satisfying (M) and (TI).

• VaR and ES are monetary and law-invariant.

### A simplified example:

- $\Omega = \{\omega_1, \omega_2, \omega_3\}$ : future (e.g. one-year) economic states
  - $\omega_1$ : a normal economic state
  - $\omega_2$ : an adverse economic state
  - $\omega_3$ : an extreme scenario
- $\mathbb{P}(\{\omega_1\}) = 0.99$ ,  $\mathbb{P}(\{\omega_2\}) = 0.0099$  and  $\mathbb{P}(\{\omega_3\}) = 0.0001$
- A financial institution has to choose between two risks (decisions)

| Risk measures | Motivating example | Consistency | Characterization | Risk sharing | Discussions | References |
|---------------|--------------------|-------------|------------------|--------------|-------------|------------|
| 0000000       | 0●0000             | 000000      |                  | 00           | 00          | 00         |
| Simple I      | Example            |             |                  |              |             |            |

Risks X and Y (in millions of USD):

$$X = \begin{cases} -1 & \omega = \omega_1, \\ 10 & \omega = \omega_2, \\ 20 & \omega = \omega_3, \end{cases} \quad Y = \begin{cases} -1.1 & \omega = \omega_1, \\ 9.9 & \omega = \omega_2, \\ 2,000 & \omega = \omega_3. \end{cases}$$

- Possible interpretations:
  - X is benchmark Y is X plus an bet against event ω<sub>3</sub> (e.g. AAA bond with high leverage)
  - Y is benchmark X is Y plus a hedge against event ω<sub>3</sub> (e.g. insurance contract)

• 
$$\mathbb{P}(Y < X) = 99.99\%$$

- Assume that the financial institution has 10M (economic) capital
  - $VaR_{0.999}(X) = 10$ ,  $VaR_{0.999}(Y) = 9.9$
- Which risk would the financial institution prefer?
  - The manager of the financial institution is not necessarily risk averse
  - Limited liability
  - $\mathbb{P}(\omega_3)$  is too small to notice or accurately model
- Which risk would a regulator prefer?
  - A regulator cares about loss to the society
  - What if all firms in the system are doing this? ... Aggregation!

Risk measuresMotivating example<br/>000000ConsistencyCharacterization<br/>0000000Risk sharingDiscussionsReferences0000000000000000000000000000000

### Financial Decisions and Risk Preference

### Question

How can the regulator leads/encourages the financial institution to choose X over Y?

Idea:

(1) A firm has incentives to reduce its regulatory capital

- Firms are "effectively risk averse" because holding capital is costly
- Froot-Stein (1998), Zanjani (2002), Bauer-Zanjani (2016)
- (2) View a regulatory risk measure  $\rho$  as a decision principle for the firm
- (3) Choose a properly designed  $\rho$

### Risk measures Motivating example Consistency Characterization Risk sharing Discussions References 000000 000000 00000000 00 00 00 00

### Financial Decisions and Risk Preference

A regulator uses  $\rho$  to calculate regulatory capital

- Formally, assume that for two decisions X and Y, if
   ρ(X) ≪ ρ(Y), then a firm has the incentive to choose X
   (smaller capital) over Y (larger capital).
- If the regulator prefers X to Y, then she should design ρ such that ρ(X) < ρ(Y).</li>
- In the previous example

|                       | X     | Y      |
|-----------------------|-------|--------|
| $VaR_{0.999}$         | 10    | 9.9    |
| $\mathrm{ES}_{0.999}$ | 11    | 208.91 |
| StDev                 | 1.109 | 20.039 |

Expected Loss to the Society

A company has capital K and decides between two risks  $X, Y \in \mathcal{X} \subset L^1.$ 

- If E[(X − K)<sub>+</sub>] ≤ E[(Y − K)<sub>+</sub>] then taking X has less expected loss to the society.
- If E[(X − K)<sub>+</sub>] ≤ E[(Y − K)<sub>+</sub>] holds for all K, then it is reasonable that X requires a smaller capital.

Formally, define the property

(EL) Consistency with expected loss to the society: for  $X, Y \in \mathcal{X}$ ,  $\rho(X) \le \rho(Y)$  if  $\mathbb{E}[(X - K)_+] \le \mathbb{E}[(Y - K)_+]$  for all  $K \in \mathbb{R}$ .

(EL) is equivalent to the consistency with respect to second-order stochastic dominance (SSD).

| Risk Ave      | ersion             |             |                  |              |             |            |

### Definition 2 (Second-order stochastic dominance)

For  $X, Y \in L^1$ , X has second-order stochastic dominance (SSD) over Y, denoted as  $X \prec_{sd} Y$ , if  $\mathbb{E}[f(X)] \leq \mathbb{E}[f(Y)]$  for all increasing convex functions f such that the expectations exist.

- Also known as increasing convex order or stop-loss order
- $X \prec_{\mathrm{sd}} Y$  in the previous three-state example

(SC) SSD consistentcy:  $\rho(X) \leq \rho(Y)$  if  $X \prec_{sd} Y, X, Y \in \mathcal{X}$ .

- (SC) is called strong risk aversion in decision theory
- (SC) ⇔ (EL)

Assume  $\mathcal{X} \subset L^1$  in the following.

Definition 3 (Consistent risk measures)

A risk measure is a consistent risk measure if it satisfies (SC) and (TI).

- Consistent risk measures are monetary
- Interpretation: the regulator penalizes more risky financial decisions (ones that have higher expected social impact)

### Some examples

- An Expected Shortfall  $\text{ES}_p$ ,  $p \in (0, 1)$  is consistent
- The mean  $\mathbb{E}[\cdot]$  on  $L^1$  is consistent
- Any law-invariant convex risk measure on  $L^{\infty}$  is consistent
- Any finite law-invariant convex risk measure on  $L^q$ , q > 1 is consistent
- Any Value-at-Risk  $\operatorname{VaR}_p$ ,  $p \in (0, 1)$  is not consistent
- Is a consistent risk measure necessarily convex?

### Characterization of Consistent Risk Measures

The next question is a characterization of all consistent risk measures.

- We assume  $\mathcal{X} = L^{\infty}$  for simplicity
- All results hold for  $\mathcal{X} = L^q$ ,  $q \geq 1$

### Characterization Theorem

### Theorem 5

A risk measure  $\rho$  on  $L^{\infty}$  is consistent if and only if there exists a set  $\mathcal{G}$  of functions mapping (0,1) to  $(-\infty,\infty]$  such that

$$\rho(X) = \inf_{g \in \mathcal{G}} \sup_{\rho \in (0,1)} \left\{ \operatorname{ES}_{\rho}(X) - g(\rho) \right\}, \quad X \in L^{\infty}.$$
(1)

- Example: If  $\rho$  is  $\text{ES}_p$  ( $p \in (0, 1)$ ), then one can take  $\mathcal{G} = \{g_p\}$ where  $g_p(p) = 0$  and  $g_p(x) = \infty$  for  $x \in (0, 1) \setminus p$ .
- G in (1) is not unique. It may be chosen as the adjustment set of ρ

$$\mathcal{G} = \{g_Y: Y \in \mathcal{X}, \rho(Y) \leq 0\},\$$

where  $g_Y: (0,1) \to \mathbb{R}, \ p \mapsto \mathrm{ES}_p(Y).$ 

| Risk measures<br>0000000 | Motivating example | Consistency<br>000000 | Characterization | Risk sharing<br>00 | Discussions<br>00 | References<br>00 |
|--------------------------|--------------------|-----------------------|------------------|--------------------|-------------------|------------------|
| Charact                  | erization Th       | eorem                 |                  |                    |                   |                  |

On the representation:

$$\rho(X) = \inf_{g \in \mathcal{G}} \sup_{p \in (0,1)} \left\{ \operatorname{ES}_p(X) - g(p) \right\}, \ X \in L^{\infty}.$$

- $g \in \mathcal{G}$  are benchmarks: if for some  $g \in \mathcal{G}$ , ES.(X)  $\leq g(\cdot)$ , then  $\rho(X) \leq 0$  (an accepted risk without extra capital); otherwise  $\rho(X) > 0$  (or > 0).
- Any risk-averse regulator or risk manager is essentially using a collection of Expected Shortfalls up to some adjustments.

### Relation to Classic Risk Measures

Classic properties in the theory of monetary risk measures

- (PH) Positive homogeneity:  $\rho(\lambda X) = \lambda \rho(X)$  for all  $\lambda \in (0, \infty)$  and  $X \in \mathcal{X}$ ;
- (CX) Convexity:  $\rho(\lambda X + (1 \lambda)Y) \le \lambda \rho(X) + (1 \lambda)\rho(Y)$  for all  $\lambda \in [0, 1]$  and  $X, Y \in \mathcal{X}$ ;

(CA) Comonotonic additivity:  $\rho(X + Y) = \rho(X) + \rho(Y)$  if  $(X, Y) \in \mathcal{X}^2$  is comonotonic.

### Definition 6

A risk measure is called a convex risk measure if it satisfies (M), (TI) and (CX). A risk measure is called a coherent risk measure if it satisfies (M), (TI), (PH) and (CX).

(Artzner-Delbaen-Eber-Heath 1999, Föllmer-Schied 2002, Kusuoka 2001)≣→ 🛛 🗟 – 🕫 🕫

### Relation to Classic Risk Measures

Consistent risk measures are closely related to law-invariant convex risk measures.

#### Theorem 7

A risk measure  $\rho$  on  $L^{\infty}$  is consistent if and only if there exists a set C of law-invariant convex risk measures such that

$$\rho(X) = \inf_{\tau \in \mathcal{C}} \tau(X), \quad X \in L^{\infty}.$$

### Relation to Classic Risk Measures

Yet we obtain a new characterization of convex (coherent) risk measures.

### Proposition 8

A law-invariant risk measure  $\rho$  on  $L^{\infty}$  is a convex (resp. coherent) risk measure if and only if there exists a convex set (resp. convex cone)  $\mathcal{G}$  of functions mapping (0,1) to  $(-\infty,\infty]$  such that

$$\rho(X) = \inf_{g \in \mathcal{G}} \sup_{p \in (0,1)} \left\{ \operatorname{ES}_p(X) - g(p) \right\}, \ X \in L^{\infty}.$$

|                          |  |  |  |  |  | 00 |  |  |
|--------------------------|--|--|--|--|--|----|--|--|
| Consistency vs Convexity |  |  |  |  |  |    |  |  |

Consistency versus convexity:

- (SC) Consistentcy:  $\rho(X) \leq \rho(Y)$  if  $X \prec_{\mathrm{sd}} Y$ ,  $X, Y \in \mathcal{X}$ .
- (CX) Convexity:  $\rho(\lambda X + (1 \lambda)Y) \le \lambda \rho(X) + (1 \lambda)\rho(Y)$  for all  $\lambda \in [0, 1]$  and  $X, Y \in \mathcal{X}$ .
  - (i) Consistency compares between risks (decisions) while convexity does not
  - (ii) For risk-types other than market risk, portfolio diversification is not appropriate
  - (iii) There is no direct reason why a regulator would favour diversification in a single company, unless some social benefit could be expected (cf. Ibragimov-Jaffee-Walden 2011)

| Kusuoka Representations |        |        |           |    |    |    |  |  |

Kusuoka Representations

- Let *P* be the set of all probability measures on [0, 1] and *U* be the set of all functions mapping *P* to ℝ.
- A law-invariant coherent risk measure  $\rho$  on  $L^\infty$  has the following representation

$$ho = \sup_{h \in \mathcal{R}} \left\{ \int_0^1 \mathrm{ES}_p \mathrm{d}h(p) 
ight\} \quad ext{for some } \mathcal{R} \subset \mathcal{P}.$$

• A law-invariant convex risk measure  $\rho$  on  $L^{\infty}$  has the following representation

$$\rho = \sup_{h \in \mathcal{P}} \left\{ \int_0^1 \mathrm{ES}_p \mathrm{d}h(p) - \alpha(h) \right\} \quad \text{for some } \alpha \in \mathcal{U}.$$

# Risk measures Motivating example Consistency Characterization Risk sharing Discussions References 000000 0000000 0000000 00 00 00 00 00 Kusuoka Representations 000000 00 00 00 00 00

Grand summary: for a risk measure on  $L^{\infty}$ ,

$$\begin{aligned} (\mathsf{TI})+(\mathsf{SC}) &= \inf_{\alpha \in \mathcal{V}} \sup_{h \in \mathcal{P}} \left\{ \int_0^1 \mathrm{ES}_p \mathrm{d}h(p) - \alpha(h) \right\} & \text{for some } \mathcal{V} \subset \mathcal{U} \\ & \stackrel{+(\mathsf{CX})}{\longrightarrow} \sup_{h \in \mathcal{P}} \left\{ \int_0^1 \mathrm{ES}_p \mathrm{d}h(p) - \alpha(h) \right\} & \text{for some } \alpha \in \mathcal{U} \\ & \stackrel{+(\mathsf{PH})}{\longrightarrow} \sup_{h \in \mathcal{R}} \left\{ \int_0^1 \mathrm{ES}_p \mathrm{d}h(p) \right\} & \text{for some } \mathcal{R} \subset \mathcal{P} \\ & \stackrel{+(\mathsf{CA})}{\longrightarrow} \int_0^1 \mathrm{ES}_p \mathrm{d}h(p) & \text{for some } h \in \mathcal{P}. \end{aligned}$$

Remark: (TI)+(SC)+(CA) is sufficient for the last representation

### General setup

- *n* agents sharing a total risk  $X \in \mathcal{X}$
- $\rho_1, \ldots, \rho_n$ : underlying risk measures

Target: for  $X \in \mathcal{X}$ , find an Pareto-optimal solution of X to minimize

$$\rho_1(X_1),\ldots,\rho_n(X_n) \tag{2}$$

over the set of all allocations:

$$\mathbb{A}_n(X) = \left\{ (X_1, \ldots, X_n) \in \mathcal{X}^n : \sum_{i=1}^n X_i = X \right\}.$$

| Risk Sharing |        |        |          |    |    |    |  |  |

### Theorem 9

Suppose that  $\rho_1, \ldots, \rho_n$  are consistent risk measures on  $\mathcal{X} = L^q$ ,  $q \in [1, \infty]$  with adjustment sets  $\mathcal{G}_1, \ldots, \mathcal{G}_n$ , respectively. An allocation  $(X_1, \ldots, X_n) \in \mathbb{A}_n(X)$  is Pareto-optimal if and only if

$$\sum_{i=1}^n \rho_i(X_i) = \rho^*(X),$$

where  $\rho^*$  is a consistent risk measure with adjustment set  $\sum_{i=1}^n \mathcal{G}_i$ .

In particular,

$$\rho^*(X) = \inf_{g \in \mathcal{G}_1 + \dots + \mathcal{G}_n} \sup_{\alpha \in [0,1]} \left\{ \operatorname{ES}_{\alpha}(X) - g(\alpha) \right\}, \quad X \in \mathcal{X}.$$

### Suitable risk measures for regulation

On the current debates regarding the desirability of VaR and ES:

- A suitable risk measure applied in regulatory practice should encourage prudent and socially responsible financial decisions
  - Financial institutions are not necessarily risk-averse or socially responsible for their own interest; a regulator should push them towards risk-aversion
- ES is the basis for any consistent risk measure supporting the transition from VaR to ES in the recent Basel documents
- ES is the only candidate which preserves consistency and also has simple form and clear economic interpretation

### Suitable risk measures for regulation

Further remarks:

- Consistency is more natural than convexity for a regulator
- One can construct non-convex consistent risk measures
  - As far as we are aware of, there are no non-convex consistent risk measures in simple analytical forms other than a minimum
- Criteria for a desirable risk measure used in banking and insurance regulation may vary
- Bring more in decision theory to risk measures and regulation
